LM43602 SIMPLE SWITCHER® 3.5 V to 36 V 2-A Synchronous Step-Down Voltage Converter

1 Features

- 27 µA Quiescent Current in Regulation
- High Efficiency at Light Load (DCM and PFM)
- Meets EN55022/CISPR 22 EMI standards
- Integrated Synchronous Rectification
- Adjustable Frequency Range: 200 kHz to 2.2 MHz (500 kHz default)
- Frequency Synchronization to External Clock
- Internal Compensation
- Stable with Almost Any Combination of Ceramic, Polymer, Tantalum, and Aluminum Capacitors
- Power-Good Flag
- Soft-Start into a Pre-Biased Load
- Internal Soft-Start: 4.1 ms
- Extendable Soft-Start Time by External Capacitor
- Output Voltage Tracking Capability
- Precision Enable to Program System UVLO
- Output Short Circuit Protection with Hiccup Mode
- Over Temperature Thermal Shutdown Protection

2 Applications

- Industrial Power Supplies
- Telecommunications Systems
- Sub-AM Band Automotive
- General Purpose Wide V_{IN} Regulation
- High Efficiency Point-Of-Load Regulation

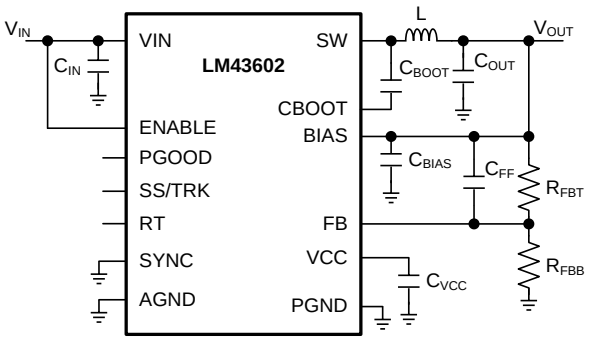

3 Description

The LM43602 SIMPLE SWITCHER® regulator is an easy to use synchronous step-down DC-DC converter capable of driving up to 2 A of load current from an input voltage ranging from 3.5 V to 36 V (42V abs max). The LM43602 provides exceptional efficiency, output accuracy and dropout voltage in a very small solution size. An extended family is available in 0.5 A , 1 A, and 3 A load current options in pin to pin compatible packages. Peak current mode control is employed to achieve simple control loop compensation and cycle-by-cycle current limiting. Optional features such as programmable switching frequency, synchronization, power-good flag, precision enable, internal soft-start, extendable soft-start, and tracking provide a flexible and easy to use platform for a wide range of applications. Discontinuous conduction and automatic frequency modulation at light loads improve light load efficiency. The family requires few external components and terminal arrangement allows simple, optimum PCB layout. Protection features include thermal shutdown, V_{CC} under-voltage lockout, cycle-by-cycle current limit, and output short circuit protection. The LM43602 device is available in the HTSSOP / PWP 16 leaded package (5.1mm x 6.6mm x1.2mm).

6 Pin Configuration and Functions

16-Pin HTSSOP (PWP)
Top View

Pin Functions

PIN		DESCRIPTION
NAME	NUMBER	
SW	1,2	Switching output of the regulator. Internally connected to both power MOSFETs. Connect to power inductor.
CBOOT	3	Boot-strap capacitor connection for high-side driver. Connect a high quality 470 nF capacitor from CBOOT to SW.
VCC	4	Internal bias supply output for bypassing. Connect bypass capacitor from this pin to AGND. Do not connect external loading to this pin. Never short this pin to ground during operation.
BIAS	5	Optional internal LDO supply input. To improve efficiency, it is recommended to tie to V_{OUT} when 3.3 V ≤ V_{OUT} ≤ 28 V, or tie to an external 3.3 V or 5 V rail if available. When used, place a bypass capacitor (1 to 10 µF) from this pin to ground. Tie to ground when not in use.
SYNC	6	Clock input to synchronize switching action to an external clock. Use proper high speed termination to prevent ringing. Connect to ground if not used.
RT	7	Connect a resistor R_T from this pin to AGND to program switching frequency. Leave floating for 500 kHz default switching frequency.
PGOOD	8	Open drain output for power-good flag. Use a 10 kΩ to 100 kΩ pull-up resistor to logic rail or other DC voltage no higher than 12 V.
FB	9	Feedback sense input pin. Connect to the midpoint of feedback divider to set V_{OUT}. Do not short this pin to ground during operation.
AGND	10	Analog ground pin. Ground reference for internal references and logic. Connect to system ground.
SS/TRK	11	Soft-start control pin. Leave floating for internal soft-start slew rate. Connect to a capacitor to extend soft start time. Connect to external voltage ramp for tracking.
EN	12	Enable input to the internal LDO and regulator. High = ON and low = OFF. Connect to VIN, or to VIN through resistor divider,or to an external voltage or logic source. Do not float.
VIN	13,14	Supply input pins to internal LDO and high side power FET. Connect to power supply and bypass capacitors C_{IN}. Path from VIN pin to high frequency bypass C_{IN} and PGND must be as short as possible.
PGND	15,16	Power ground pins, connected internally to the low side power FET. Connect to system ground, PAD, AGND, ground pins of C_{IN} and C_{OUT}. Path to C_{IN} must be as short as possible.
PAD	17	Low impedance connection to AGND. Connect to PGND on PCB. Major heat dissipation path of the die. Must be used for heat sinking to ground plane on PCB.

7 Specifications

7.1 Absolute Maximum Ratings(1)

Over operating free-air temperature range (unless otherwise noted)

	PARAMETER	MIN	MAX	UNIT
Input Voltages	VIN to PGND	-0.3	42(2)	V
	EN to PGND	-0.3	VIN+0.3	
	FB, RT, SS/TRK to AGND	-0.3	3.6	
	PGOOD to AGND	-0.3	15	
	SYNC to AGND	-0.3	5.5	
	BIAS to AGND	-0.3	30	
	AGND to PGND	-0.3	0.3	
Output Voltages	SW to PGND	-0.3	VIN+0.3	V
	SW to PGND less than 10ns Transients	-3.5	42	
	CBOOT to SW	-0.3	5.5	
	VCC to AGND	-0.3	3.6	
Operating Junction Temperature T_J		-40	+125	°C

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under Recommended Operating Conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) At max duty cycle of 0.01%

7.2 Handling Ratings

PARAMETER	DEFINITION	MIN	MAX	UNIT
T_{stg}	Storage temperature range	-65	+150	°C
V_{ESD} (1)(2)	HBM Human body model		1.0	kV
	CDM Charge device model		0.5	

(1) Electrostatic discharge (ESD) to measure device sensitivity/immunity to damage caused by assembly line electrostatic discharges into the device.
(2) ESD testing is performed according to the respective JESD22 JEDEC standard.

7.3 Recommended Operating Conditions(1)

Over operating free-air temperature range (unless otherwise noted)

	PARAMETER	MIN	MAX	UNIT
Input Voltages	VIN to PGND	3.5	36	V
	EN	-0.3	VIN	
	FB	-0.3	1.1	
	PGOOD	-0.3	12	
	BIAS input not used	-0.3	0.3	
	BIAS input used	3.3	28	
	AGND to PGND	-0.1	0.1	
Output Voltage	V_{OUT}	1.0	28	V
Output Current	I_{OUT}	0	2	A
Temperature	Operating junction temperature range, T_J	-40	+125	°C

(1) Operating Ratings indicate conditions for which the device is intended to be functional, but do not guarantee specific performance limits. For guaranteed specifications, see Electrical Characteristics.

7.4 Thermal Information

THERMAL METRIC (1)(2)		HTSSOP (16 PINS)	UNIT
$R_{\theta JA}$	Junction-to-ambient thermal resistance	38.9 (3)	°C/W
$R_{\theta JC(top)}$	Junction-to-case (top) thermal resistance	24.3	
$R_{\theta JB}$	Junction-to-board thermal resistance	19.9	
ψ_{JT}	Junction-to-top characterization parameter	0.7	
ψ_{JB}	Junction-to-board characterization parameter	19.7	
$R_{\theta JC(bot)}$	Junction-to-case (bottom) thermal resistance	1.7	

(1) The package thermal impedance is calculated in accordance with JESD 51-7;
(2) Thermal Resistances were simulated on a 4 layer, JEDEC board.
(3) See Figure 64 for θ_{JA} vs Copper Area Curve

7.5 Electrical Characteristics

Limits apply over the recommended operating junction temperature (T_J) range of -40°C to +125°C, unless otherwise stated. Minimum and Maximum limits are specified through test, design or statistical correlation. Typical values represent the most likely parametric norm at T_J = 25°C, and are provided for reference purposes only. Unless otherwise stated, the following conditions apply: V_{IN} = 12 V, V_{OUT} = 3.3 V, F_S = 500 kHz.

SYMBOL	PARAMETER	CONDITIONS	MIN	TYP	MAX	UNIT
SUPPLY VOLTAGE (VIN PIN)						
$V_{IN-MIN-ST}$	Minimum input voltage for startup				3.8	V
I_{SHDN}	Shutdown quiescent current	V_{EN} = 0 V		1.2	3.1	µA
$I_{Q-NONSW}$	Operating quiescent current (non-switching) from V_{IN}	V_{EN} = 3.3 V V_{FB} = 1.5 V V_{BIAS} = 3.4 V external		5.0	10	µA
$I_{BIAS-NONSW}$	Operating quiescent current (non-switching) from external V_{BIAS}	V_{EN} = 3.3 V V_{FB} = 1.5 V V_{BIAS} = 3.4 V external		85	130	µA
I_{Q-SW}	Operating quiescent current (switching)	V_{EN} = 3.3 V I_{OUT} = 0 A R_T = open V_{BIAS} = V_{OUT} = 3.3 V R_{FBT} = 1.0 Meg		27		µA
ENABLE (EN PIN)						
$V_{EN-VCC-H}$	Voltage level to enable the internal LDO output V_{CC}	V_{ENABLE} high level	1.2			V
$V_{EN-VCC-L}$	Voltage level to disable the internal LDO output V_{CC}	V_{ENABLE} low level			0.525	V
$V_{EN-VOUT-H}$	Precision enable level for switching and regulator output: V_{OUT}	V_{ENABLE} high level	2.00	2.2	2.42	V
$V_{EN-VOUT-HYS}$	Hysteresis voltage between V_{OUT} precision enable and disable thresholds	V_{ENABLE} hysteresis		-290		mV
I_{LKG-EN}	Enable input leakage current	V_{EN} = 3.3 V		0.85	1.75	µA
INTERNAL LDO (VCC and BIAS PINS)						
V_{CC}	Internal LDO output voltage V_{CC}	V_{IN} ≥ 3.8 V		3.28		V
$V_{CC-UVLO}$	Under voltage lock out (UVLO) thresholds for V_{CC}	V_{CC} rising threshold		3.1		V
		Hysteresis voltage between rising and falling thresholds		-520		mV
$V_{BIAS-ON}$	Internal LDO input change over threshold to BIAS	V_{BIAS} rising threshold		2.94	3.15	V
		Hysteresis voltage between rising and falling thresholds		-75		mV

Electrical Characteristics (continued)

Limits apply over the recommended operating junction temperature (T_J) range of -40°C to +125°C, unless otherwise stated. Minimum and Maximum limits are specified through test, design or statistical correlation. Typical values represent the most likely parametric norm at T_J = 25°C, and are provided for reference purposes only. Unless otherwise stated, the following conditions apply: V_{IN} = 12 V, V_{OUT} = 3.3 V, F_S = 500 kHz.

SYMBOL	PARAMETER	CONDITIONS	MIN	TYP	MAX	UNIT
VOLTAGE REFERENCE (FB PIN)						
V_{FB}	Feedback voltage	T_J = 25 ºC	1.004	1.011	1.018	V
		T_J = -40 ºC to 85 ºC	0.994	1.011	1.026	
		T_J = -40 ºC to 125 ºC	0.994	1.011	1.030	
I_{LKG-FB}	Input leakage current at FB pin	FB = 1.0 V		0.2	65	nA
THERMAL SHUTDOWN						
T_{SD} (1)	Thermal shutdown	Shutdown threshold		160		ºC
		Recovery threshold		150		ºC
CURRENT LIMIT AND HICCUP						
$I_{HS-LIMIT}$	Peak inductor current limit		3.65	4.5	5.15	A
$I_{LS-LIMIT}$	Inductor current valley limit		1.75	2.0	2.25	A
SOFT START (SS/TRK PIN)						
I_{SSC}	Soft-start charge current		1.25	2.0	2.75	µA
R_{SSD}	Soft-start discharge resistance	UVLO, TSD, OCP, or EN = 0 V		18		kΩ
POWER GOOD (PGOOD PIN)						
$V_{PGOOD-HIGH}$	Power-good flag over voltage tripping threshold	% of FB voltage		110%	113%	
$V_{PGOOD-LOW}$	Power-good flag under voltage tripping threshold	% of FB voltage	77%	88%		
$V_{PGOOD-HYS}$	Power-good flag recovery hysteresis	% of FB voltage		6%		
R_{PGOOD}	PGOOD pin pull down resistance when power bad	V_{EN} = 3.3 V		40	125	Ω
		V_{EN} = 0 V		60	150	
MOSFETS (2)						
$R_{DS-ON-HS}$	High-side MOSFET ON-resistance	I_{OUT} = 1 A V_{BIAS} = V_{OUT} = 3.3 V		120		mΩ
$R_{DS-ON-LS}$	Low-side MOSFET ON-resistance	I_{OUT} = 1 A V_{BIAS} = V_{OUT} = 3.3 V		65		mΩ

(1) Guaranteed by design
(2) Measured at the pins

7.6 Timing Requirements

		MIN	TYP	MAX	UNIT
CURRENT LIMIT AND HICCUP					
N_{OC}	Hiccup wait cycles when LS current limit tripped		32		Cycles
T_{OC}	Hiccup retry delay time		5.5		ms
SOFT START (SS/TRK PIN)					
T_{SS}	Internal soft-start time when SS pin open circuit		4.1		ms
POWER GOOD (PGOOD PIN)					
$T_{PGOOD-RISE}$	Power-good flag rising transition deglitch delay		220		µs
$T_{PGOOD-FALL}$	Power-good flag falling transition deglitch delay		220		µs

8 Detailed Description

8.1 Overview

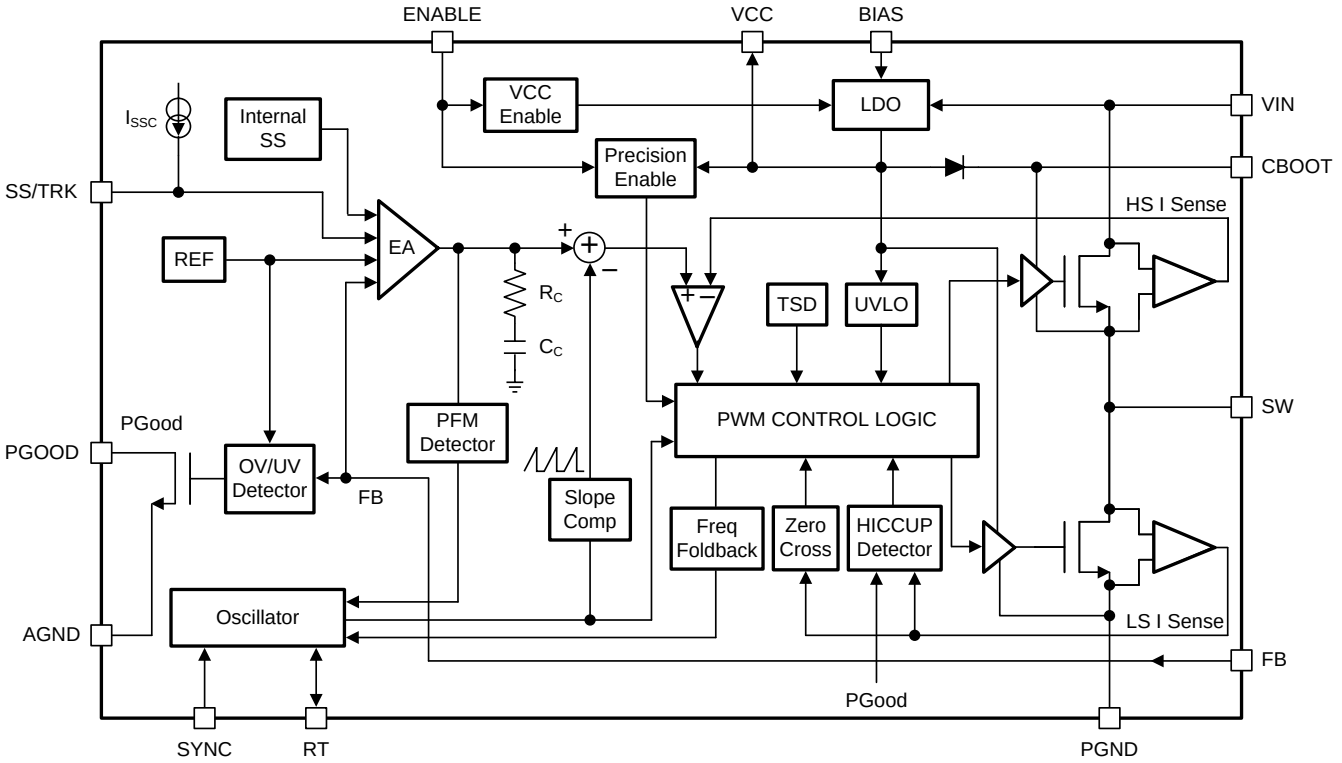

The LM43602 Simple Switcher® regulator is an easy to use synchronous step-down DC-DC converter that operates from 3.5 V to 36 V supply voltage. It is capable of delivering up to 2 A DC load current with exceptional efficiency and thermal performance in a very small solution size. An extended family is available in 0.5 A, 1A, and 3 A load options in pin to pin compatible packages.

The LM43602 employs fixed frequency peak current mode control with Discontinuous Conduction Mode (DCM) and Pulse Frequency Modulation (PFM) mode at light load to achieve high efficiency across the load range. The device is internally compensated, which reduces design time, and requires fewer external components. The switching frequency is programmable from 200 kHz to 2.2 MHz by an external resistor R_T. It is default at 500 kHz without R_T resistor. The LM43602 is also capable of synchronization to an external clock within the 200 kHz to 2.2 MHz frequency range. The wide switching frequency range allows the device to be optimized to fit small board space at higher frequency, or high efficient power conversion at lower frequency.

Optional features are included for more comprehensive system requirements, including power-good (PGOOD) flag, precision enable, synchronization to external clock, extendable soft-start time, and output voltage tracking. These features provide a flexible and easy to use platform for a wide range of applications. Protection features include over temperature shutdown, V_{CC} under-voltage lockout (UVLO), cycle-by-cycle current limit, and short-circuit protection with hiccup mode.

The family requires few external components and the pin arrangement was designed for simple, optimum PCB layout. The LM43602 device is available in the HTSSOP / PWP 16 pins leaded package.

8.2 Functional Block Diagram

Copyright © 2014, Texas Instruments Incorporated

8.3 Feature Description

8.3.1 Fixed Frequency Peak Current Mode Controlled Step-Down Regulator

The following operating description of the LM43602 will refer to the Functional Block Diagram and to the waveforms in Figure 25. The LM43602 is a step-down Buck regulator with both high-side (HS) switch and low-side (LS) switch (synchronous rectifier) integrated. The LM43602 supplies a regulated output voltage by turning on the HS and LS NMOS switches with controlled ON time. During the HS switch ON time, the SW pin voltage V_{SW} swings up to approximately V_{IN}, and the inductor current i_L increases with a linear slope (V_{IN} - V_{OUT}) / L. When the HS switch is turned off by the control logic, the LS switch is turned on after a anti-shoot-through dead time. Inductor current discharges through the LS switch with a slope of -V_{OUT} / L. The control parameter of Buck converters are defined as Duty Cycle D = t_{ON} / T_{SW}, where t_{ON} is the HS switch ON time and T_{SW} is the switching period. The regulator control loop maintains a constant output voltage by adjusting the duty cycle D. In an ideal Buck converter, where losses are ignored, D is proportional to the output voltage and inversely proportional to the input voltage: D = V_{OUT} / V_{IN}.

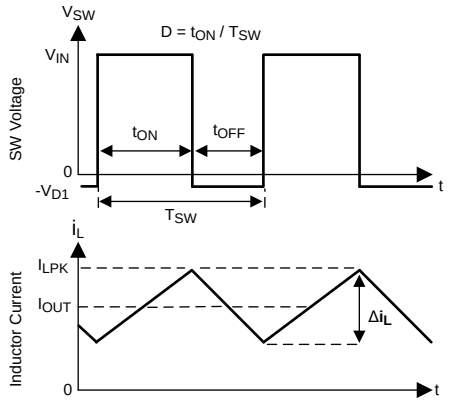

Figure 25. SW Node and Inductor Current Waveforms in Continuous Conduction Mode (CCM)

The LM43602 synchronous Buck converter employs peak current mode control topology. A voltage feedback loop is used to get accurate DC voltage regulation by adjusting the peak current command based on voltage offset. The peak inductor current is sensed from the HS switch and compared to the peak current to control the ON time of the HS switch. The voltage feedback loop is internally compensated, which allows for fewer external components, makes it easy to design, and provides stable operation with almost any combination of output capacitors. The regulator operates with fixed switching frequency in Continuous Conduction Mode (CCM) and Discontinuous Conduction Mode (DCM). At very light load, the LM43602 will operate in PFM to maintain high efficiency and the switching frequency will decrease with reduced load current.

8.3.2 Light Load Operation

DCM operation is employed in the LM43602 when the inductor current valley reaches zero. The LM43602 will be in DCM when load current is less than half of the peak-to-peak inductor current ripple in CCM. In DCM, the LS switch is turned off when the inductor current reaches zero. Switching loss is reduced by turning off the LS FET at zero current and the conduction loss is lowered by not allowing negative current conduction. Power conversion efficiency is higher in DCM than CCM under the same conditions.

In DCM, the HS switch ON time will reduce with lower load current. When either the minimum HS switch ON time (t_{ON-MIN}) or the minimum peak inductor current ($I_{PEAK-MIN}$) is reached, the switching frequency will decrease to maintain regulation. At this point, the LM43602 operates in PFM. In PFM, switching frequency is decreased by the control loop when load current reduces to maintain output voltage regulation. Switching loss is further reduced in PFM operation due to less frequent switching actions.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

In PFM operation, a small positive DC offset is required at the output voltage to activate the PFM detector. The lower the frequency in PFM, the more DC offset is needed at V_{OUT}. Please refer to the Typical Characteristics for typical DC offset at very light load. If the DC offset on V_{OUT} is not acceptable for a given application, a static load at output is recommended to reduce or eliminate the offset. Lowering values of the feedback divider R_{FBT} and R_{FBB} can also serve as a static load. In conditions with low VIN and/or high frequency, the LM43602 may not enter PFM mode if the output voltage cannot be charged up to provide the trigger to activate the PFM detector. Once the LM43602 is operating in PFM mode at higher V_{IN}, it will remain in PFM operation when VIN is reduced

8.3.3 Adjustable Output Voltage

The voltage regulation loop in the LM43602 regulates output voltage by maintaining the voltage on FB pin (V_{FB}) to be the same as the internal REF voltage (V_{REF}). A resistor divider pair is needed to program the ratio from output voltage V_{OUT} to V_{FB}. The resistor divider is connected from the V_{OUT} of the LM43602 to ground with the mid-point connecting to the FB pin.

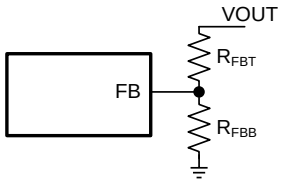

Figure 26. Output Voltage Setting

The voltage reference system produces a precise voltage reference over temperature. The internal REF voltage is 1.011 V typically. To program the output voltage of the LM43602 to be a certain value V_{OUT}, R_{FBB} can be calculated with a selected R_{FBT} by

$$R_{FBB} = \frac{V_{FB}}{V_{OUT} - V_{FB}} R_{FBT} \quad (1)$$

The choice of the R_{FBT} depends on the application. R_{FBT} in the range from 10 kΩ to 100 kΩ is recommended for most applications. A lower R_{FBT} value can be used if static loading is desired to reduce V_{OUT} offset in PFM operation. Lower R_{FBT} will reduce efficiency at very light load. Less static current goes through a larger R_{FBT} and might be more desirable when light load efficiency is critical. But R_{FBT} larger than 1 MΩ is not recommended because it makes the feedback path more susceptible to noise. Larger R_{FBT} value requires more carefully designed feedback path on the PCB. The tolerance and temperature variation of the resistor dividers affect the output voltage regulation. It is recommended to use divider resistors with 1% tolerance or better and temperature coefficient of 100 ppm or lower.

If the resistor divider is not connected properly, output voltage cannot be regulated since the feedback loop is broken. If the FB pin is shorted to ground, the output voltage will be driven close to V_{IN}, since the regulator sees very low voltage on the FB pin and tries to regulator it up. The load connected to the output could be damaged under such a condition. Do not short FB pin to ground when the LM43602 is enabled. It is important to route the feedback trace away from the noisy area of the PCB. For more layout recommendations, please refer to the Layout section.

8.3.4 Enable (EN)

Voltage on the EN pin (V_{EN}) controls the ON or OFF operation of the LM43602. Applying a voltage less than 0.4 V to the EN input shuts down the operation of the LM43602. In shutdown mode the quiescent current drops to typically 1.2 µA at V_{IN} = 12 V.

The internal LDO output voltage V_{CC} is turned on when V_{EN} is higher than 1.2 V. The LM43602 switching action and output regulation are enabled when V_{EN} is greater than 2.1 V (typical). The LM43602 supplies regulated output voltage when enabled and output current up to 2 A.

The EN pin is an input and cannot be open circuit or floating. The simplest way to enable the operation of the LM43602 is to connect the EN pin to VIN pins directly. This allows self-start-up of the LM43602 when V_{IN} is within the operation range.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

Many applications will benefit from the employment of an enable divider R_{ENT} and R_{ENB} in Figure 27 to establish a precision system UVLO level for the stage. System UVLO can be used for supplies operating from utility power as well as battery power. It can be used for sequencing, ensuring reliable operation, or supply protection, such as a battery. An external logic signal can also be used to drive EN input for system sequencing and protection.

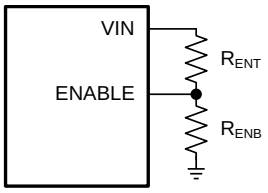

Figure 27. System UVLO By Enable Dividers

8.3.5 VCC, UVLO and BIAS

The LM43602 integrates an internal LDO to generate V_{CC} for control circuitry and MOSFET drivers. The nominal voltage for V_{CC} is 3.2 V. The VCC pin is the output of the LDO must be properly bypassed. A high quality ceramic capacitor with 2.2 µF to 10 µF capacitance and 6.3 V or higher rated voltage should be placed as close as possible to VCC and grounded to the exposed PAD and ground pins. The VCC output pin should not be loaded, left floating, or shorted to ground during operation. Shorting VCC to ground during operation may cause damage to the LM43602.

Under voltage lockout (UVLO) prevents the LM43602 from operating until the V_{CC} voltage exceeds 3.15 V (typical). The V_{CC} UVLO threshold has 575 mV of hysteresis (typically) to prevent undesired shuting down due to temperary V_{IN} droops.

The internal LDO has two inputs: primary from VIN and secondary from BIAS input. The BIAS input powers the LDO when V_{BIAS} is higher than the change-over threshold. Power loss of an LDO is calculated by I_{LDO} * (V_{IN-LDO} - $V_{OUT-LDO}$). The higher the difference between the input and output voltages of the LDO, the more power loss occur to supply the same output current. The BIAS input is designed to reduce the difference of the input and output voltages of the LDO to reduce power loss and improve LM43602 efficiency, especially at light load. It is recommended to tie the BIAS pin to V_{OUT} when V_{OUT} ≥ 3.3 V. The BIAS pin should be grounded in applications with V_{OUT} less than 3.3 V. BIAS input can also come from an external voltage source, if available, to reduce power loss. When used, a 1 µF to 10 µF high quality ceramic capacitor is recommended to bypass the BIAS pin to ground.

8.3.6 Soft-Start and Voltage Tracking (SS/TRK)

The LM43602 has a flexible and easy to use start up rate control pin: SS/TRK. Soft-start feature is to prevent inrush current impacting the LM43602 and its supply when power is first applied. Soft-start is achieved by slowly ramping up the target regulation voltage when the device is first enabled or powered up.

The simplest way to use the part is to leave the SS/TRK pin open circuit or floating. The LM43602 will employ the internal soft-start control ramp and start up to the regulated output voltage in 4.1 ms typically.

In applications with a large amount of output capacitors, or higher V_{OUT}, or other special requirements the soft-start time can be extended by connecting an external capacitor C_{SS} from SS/TRK pin to AGND. Extended soft-start time further reduces the supply current needed to charge up output capacitors and supply any output loading. An internal current source (I_{SSC} = 2.2 µA) charges C_{SS} and generates a ramp from 0 V to V_{FB} to control the ramp-up rate of the output voltage. For a desired soft start time t_{SS}, the capacitance for C_{SS} can be found by

$$C_{SS} = I_{SSC} \times t_{SS} \quad (2)$$

The LM43602 is capable of start up into prebiased output conditions. When the inductor current reaches zero, the LS switch will be turned off to avoid negative current conduction. This operation mode is also called diode emulation mode. It is built-in by the DCM operation in light loads. With prebiased output voltage, the LM43602 will wait until the soft-start ramp allows regulation above the prebiased voltage and then follow the soft-start ramp to regulation level.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

When an external voltage ramp is applied to the SS/TRK pin, the LM43602 FB voltage follows the ramp if the ramp magnitude is lower than the internal soft-start ramp. A resistor divider pair can be used on the external control ramp to the SS/TRK pin to program the tracking rate of the output voltage. The final voltage seen by the SS/TRK pin should not fall below 1.2 V to avoid abnormal operation.

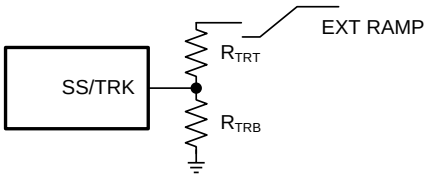

Figure 28. Soft Start Tracking External Ramp

V_{OUT} tracked to external voltage ramps has options of ramping up slower or faster than the internal voltage ramp. V_{FB} always follows the lower potential of the internal voltage ramp and the voltage on the SS/TRK pin. Figure 29 shows the case when V_{OUT} ramps slower than the internal ramp, while Figure 30 shows when V_{OUT} ramps faster than the internal ramp. Faster start up time may result in inductor current tripping current protection during start-up. Use with special care.

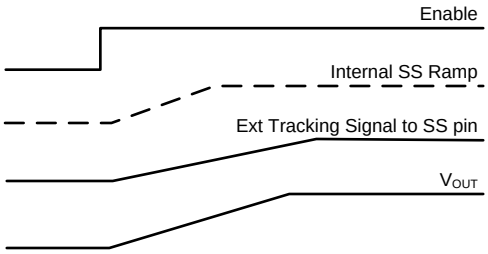

Figure 29. Tracking with Longer Start-up Time Than The Internal Ramp

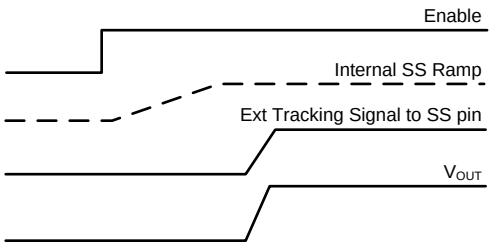

Figure 30. Tracking with Shorter Start-up Time Than The Internal Ramp

8.3.7 Switching Frequency (RT) and Synchronization (SYNC)

The switching frequency of the LM43602 can be programmed by the impedance R_T from the RT pin to ground. The frequency is inversely proportional to the R_T resistance. The RT pin can be left floating and the LM43602 will operate at 500 kHz default switching frequency. The RT pin is not designed to be shorted to ground. For a desired frequency, typical R_T resistance can be found by Equation 3. Table 1 gives typical R_T values with a given F_S.

$$R_T(k\Omega) = 40200 / \text{Freq (kHz)} - 0.6 \quad (3)$$

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

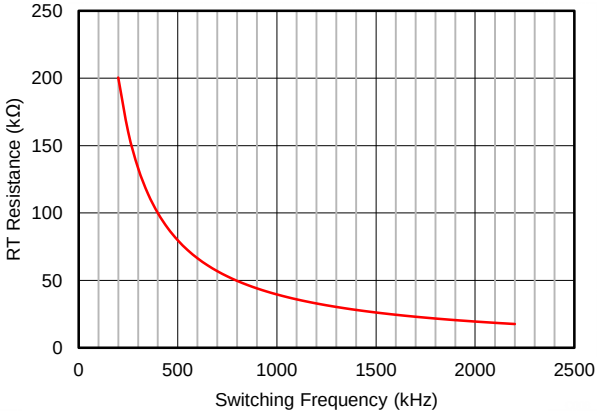

Figure 31. RT vs Frequency Curve

Table 1. Typical Frequency Setting R_T Resistance

F_S (kHz)	R_T (kΩ)
200	200
350	115
500	78.7
750	53.6
1000	39.2
1500	26.1
2000	19.6
2200	17.8

The LM43602 switching action can also be synchronized to an external clock from 200 kHz to 2.2 MHz. Connect an external clock to the SYNC pin, with proper high speed termination, to avoid ringing. The SYNC pin should be grounded if not used.

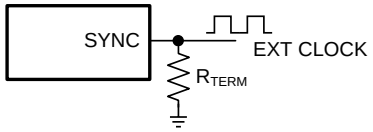

Figure 32. Frequency Synchronization

The recommendations for the external clock include: high level no lower than 2 V, low level no higher than 0.4 V, duty cycle between 10% and 90% and both positive and negative pulse width no shorter than 80 ns. When the external clock fails at logic high or low, the LM43602 will switch at the frequency programmed by the R_T resistor after a time-out period. It is recommended to connect a resistor R_T to the RT pin such that the internal oscillator frequency is the same as the target clock frequency when the LM43602 is synchronized to an external clock. This allows the regulator to continue operating at approximately the same switching frequency if the external clock fails.

The choice of switching frequency is usually a compromise between conversion efficiency and the size of the circuit. Lower switching frequency implies reduced switching losses (including gate charge losses, switch transition losses, etc.) and usually results in higher overall efficiency. However, higher switching frequency allows use of smaller LC output filters and hence a more compact design. Lower inductance also helps transient response (higher large signal slew rate of inductor current), and reduces the DCR loss. The optimal switching frequency is usually a trade-off in a given application and thus needs to be determined on a case-by-case basis. It is related to the input voltage, output voltage, most frequent load current level(s), external component choices, and circuit size requirement. The choice of switching frequency may also be limited if an operating condition triggers $T_{ON\text{-}MIN}$ or $T_{OFF\text{-}MIN}$.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

8.3.8 Minimum ON-time, Minimum OFF-time and Frequency Foldback at Drop-Out Conditions

Minimum ON-time, T_{ON-MIN}, is the smallest duration of time that the HS switch can be on. T_{ON-MIN} is typically 125 ns in the LM43602. Minimum OFF-time, $T_{OFF-MIN}$, is the smallest duration that the HS switch can be off. $T_{OFF-MIN}$ is typically 200 ns in the LM43602.

In CCM operation, T_{ON-MIN} and $T_{OFF-MIN}$ limits the voltage conversion range given a selected switching frequency. The minimum duty cycle allowed is

$$D_{MIN} = T_{ON-MIN} \times F_S \quad (4)$$

And the maximum duty cycle allowed is

$$D_{MAX} = 1 - T_{OFF-MIN} \times F_S \quad (5)$$

Given fixed T_{ON-MIN} and $T_{OFF-MIN}$, the higher the switching frequency the narrower the range of the allowed duty cycle. In the LM43602, frequency foldback scheme is employed to extend the maximum duty cycle when $T_{OFF-MIN}$ is reached. The switching frequency will decrease once longer duty cycle is needed under low VIN conditions. The switching frequency can be decreased to approximately 1/10 of the programmed frequency by R_T or the synchronization clock. Such wide range of frequency foldback allows the LM43602 output voltage stays in regulation with much lower supply voltage V_{IN}. This leads to a lower effective drop-out voltage. Please refer to Typical Characteristics for more details.

Given a output voltage, the choice of the switching frequency affects the allowed input voltage range, solution size and efficiency. The maximum operatable supply voltage can be found by

$$V_{IN-MAX} = V_{OUT} / (F_S * T_{ON-MIN}) \quad (6)$$

At lower supply voltage, the switching frequency will decrease once $T_{OFF-MIN}$ is tripped. The minimum V_{IN} without frequency foldback can be approximated by

$$V_{IN-MIN} = V_{OUT} / (1 - F_S * T_{OFF-MIN}) \quad (7)$$

Taking considerations of power losses in the system with heavy load operation, V_{IN-MIN} is higher than the result calculated in Equation 7 . With frequency foldback, V_{IN-MIN} is lowered by decreased F_S.

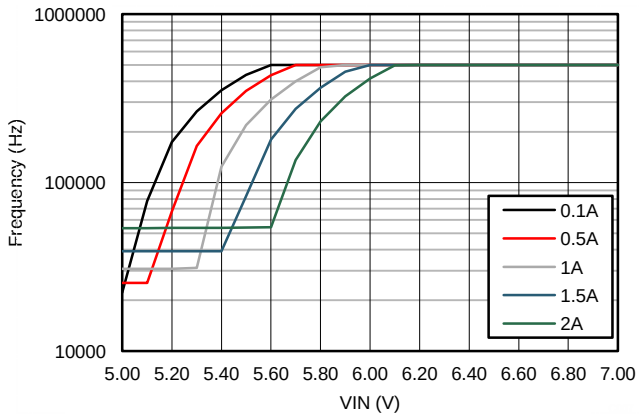

Figure 33. V_{OUT} = 5 V F_s = 500 kHz Frequency Foldback at Dropout

8.3.9 Internal Compensation and C_{FF}

The LM43602 is internally compensated with R_C = 400 kΩ and C_C = 50 pF as shown in Functional Block Diagram. The internal compensation is designed such that the loop response is stable over the entire operating frequency and output voltage range. Depending on the output voltage, the compensation loop phase margin can be low with all ceramic capacitors. An external feed-forward cap C_{FF} is recommended to be placed in parallel with the top resistor divider R_{FBT} for optimum transient performance.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

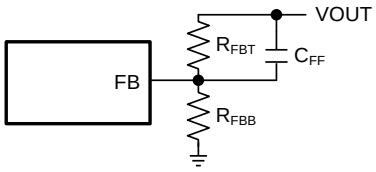

Figure 34. Feed-forward Capacitor for Loop Compensation

The feed-forward capacitor C_{FF} in parallel with R_{FBT} places an additional zero before the cross over frequency of the control loop to boost phase margin. The zero frequency can be found by

$$f_{Z\text{-}CFF} = 1 / (2\pi \times R_{FBT} \times C_{FF}). \quad (8)$$

An additional pole is also introduced with C_{FF} at the frequency of

$$f_{P\text{-}CFF} = 1 / (2\pi \times C_{FF} \times (R_{FBT} // R_{FBB})). \quad (9)$$

The C_{FF} should be selected such that the bandwidth of the control loop without the C_{FF} is centered between $f_{Z\text{-}CFF}$ and $f_{P\text{-}CFF}$. The zero $f_{Z\text{-}CFF}$ adds phase boost at the crossover frequency and improves transient response. The pole $f_{P\text{-}CFF}$ helps maintaining proper gain margin at frequency beyond the crossover.

Designs with different combinations of output capacitors need different C_{FF}. Different types of capacitors have different Equivalent Series Resistance (ESR). Ceramic capacitors have the smallest ESR and need the most C_{FF}. Electrolytic capacitors have much larger ESR and the ESR zero frequency

$$f_{Z\text{-}ESR} = 1 / (2\pi \times ESR \times C_{OUT}) \quad (10)$$

would be low enough to boost the phase up around the crossover frequency. Designs using mostly electrolytic capacitors at the output may not need any C_{FF}.

The C_{FF} creates a time constant with R_{FBT} that couples in the attenuated output voltage ripple to the FB node. If the C_{FF} value is too large, it can couple too much ripple to the FB and affect V_{OUT} regulation. It could also couple too much transient voltage deviation and falsely trip PGOOD thresholds. Therefore, C_{FF} should be calculated based on output capacitors used in the system. At cold temperatures, the value of C_{FF} might change based on the tolerance of the chosen component. This may reduce its impedance and ease noise coupling on the FB node. To avoid this, more capacitance can be added to the output or the value of C_{FF} can be reduced. Please refer to the Detailed Design Procedure for the calculation of C_{FF}.

8.3.10 Bootstrap Voltage (BOOT)

The driver of the HS switch requires a bias voltage higher than V_{IN} when the HS switch is ON. The capacitor connected between CBOOT and SW pins works as a charge pump to boost voltage on the CBOOT pin to (V_{SW} + V_{CC}). The boot diode is integrated on the LM43602 die to minimize Bill-Of-Material (BOM). A synchronous switch is also integrated in parallel with the boot diode to reduce voltage drop on CBOOT. A high quality ceramic 0.47 µF 6.3 V or higher capacitor is recommended for C_{BOOT}.

8.3.11 Power Good (PGOOD)

The LM43602 has a built in power-good flag shown on PGOOD pin to indicate whether the output voltage is within its regulation level. The PGOOD signal can be used for start-up sequencing of multiple rails or fault protection. The PGOOD pin is an open-drain output that requires a pull-up resistor to an appropriate DC voltage. Voltage seen by the PGOOD pin should never exceed 12 V. A Resistor divider pair can be used to divide voltage down from a higher potential. A typical range of pull-up resistor value is 10 kΩ to 100 kΩ.

When the FB voltage is within the power-good band, +4% above and -7% below the internal reference V_{REF} typically, the PGOOD switch will be turned off and the PGOOD voltage will be pulled up to the voltage level defined by the pull up resistor or divider. When the FB voltage is outside of the tolerance band, +10% above or -13% below V_{REF} typically, the PGOOD switch will be turned on and the PGOOD pin voltage will be pulled low to indicate power bad. Both rising and falling edges of the power-good flag have a built-in 220 µs (typical) deglitch delay.

Copyright © 2014, Texas Instruments Incorporated

Feature Description (continued)

8.3.12 Over Current and Short Circuit Protection

The LM43602 is protected from over-current conditions by cycle-by-cycle current limiting on both peak and valley of the inductor current. Hiccup mode will be activated if a fault condition persists to prevent over heating.

High-side MOSFET over-current protection is implemented by the nature of the Peak Current Mode control. The HS switch current is sensed when the HS is turned on after a set blanking time. The HS switch current is compared to the output of the Error Amplifier (EA) minus slope compensation every switching cycle. Please refer to Functional Block Diagram for more details. The peak current of the HS switch is limited by the maximum EA output voltage minus the slope compensation at every switching cycle. The slope compensation magnitude at the peak current is proportional to the duty cycle.

When the LS switch is turned on, the current going through it is also sensed and monitored. The LS switch will not be turned OFF at the end of a switching cycle if its current is above the LS current limit $I_{LS\text{-}LIMIT}$. The LS switch will be kept ON so that inductor current keeps ramping down, until the inductor current ramps below the LS current limit. Then the LS switch will be turned OFF and the HS switch will be turned on after a dead time. If the current of the LS switch is higher than the LS current limit for 32 consecutive cycles and the power-good flag is low, hiccup current protection mode will be activated. In hiccup mode, the regulator will be shutdown and kept off for 5.5 ms typically before the LM43602 tries to start again. If over-current or short-circuit fault condition still exist, hiccup will repeat until the fault condition is removed. Hiccup mode reduces power dissipation under severe over-current conditions, prevents over heating and potential damage to the device.

Hiccup is only activated when power-good flag is low. Under non-severe over-current conditions when V_{OUT} has not fallen outside of the PGOOD tolerance band, the LM43602 will reduce the switching frequency and keep the inductor current valley clamped at the LS current limit level. This operation mode allows slight over current operation during load transients without tripping hiccup. If power-good flag becomes low, hiccup operation will start after LS current limit is tripped 32 consecutive cycles.

8.3.13 Thermal Shutdown

Thermal shutdown is a built-in self protection to limit junction temperature and prevent damages due to over heating. Thermal shutdown turns off the device when the junction temperature exceeds 160°C typically to prevent further power dissipation and temperature rise. Junction temperature will reduce after thermal shutdown. The LM43602 will attempt to restart when the junction temperature drops to 150°C.

8.4 Device Functional Modes

8.4.1 Shutdown Mode

The EN pin provides electrical ON and OFF control for the LM43602. When V_{EN} is below 0.4 V, the device is in shutdown mode. Both the internal LDO and the switching regulator are off. In shutdown mode the quiescent current drops to 2.3 µA typically with V_{IN} = 24 V. The LM43602 also employs under voltage lock out protection. If V_{CC} voltage is below the UVLO level, the output of the regulator will be turned off.

8.4.2 Stand-by Mode

The internal LDO has a lower enable threshold than the regulator. When V_{EN} is above 1.2 V and below the precision enable falling threshold (1.8 V typically), the internal LDO regulates the V_{CC} voltage at 3.2 V. The precision enable circuitry is turned on once V_{CC} is above the UVLO threshold. The switching action and voltage regulation are not enabled unless V_{EN} rises above the precision enable threshold (2.1 V typically).

8.4.3 Active Mode

The LM43602 is in Active Mode when V_{EN} is above the precision enable threshold and V_{CC} is above its UVLO level. The simplest way to enable the LM43602 is to connect the EN pin to V_{IN}. This allows self start-up of the LM43602 when the input voltage is in the operation range: 3.5 V to 36 V. Please refer to Enable (EN) and VCC, UVLO and BIAS for details on setting these operating levels.

In Active Mode, depending on the load current, the LM43602 will be in one of four modes:

1. Continuous conduction mode (CCM) with fixed switching frequency when load current is above half of the peak-to-peak inductor current ripple;
2. Discontinuous conduction mode (DCM) with fixed switching frequency when load current is lower than half of

Copyright © 2014, Texas Instruments Incorporated

Device Functional Modes (continued)

the peak-to-peak inductor current ripple in CCM operation;

3. Pulse Frequency Modulation (PFM) when switching frequency is decreased at very light load;
4. Fold-back mode when switching frequency is decreased to maintain output regulation at lower supply voltage V_{IN}.

8.4.4 CCM Mode

Constant Current Mode (CCM) operation is employed in the LM43602 when the load current is higher than half of the peak-to-peak inductor current. In CCM peration, the frequency of operation is fixed unless the the minimum HS switch ON-time (T_{ON_MIN}) or OFF-time (T_{OFF_MIN}) is exceeded. Output voltage ripple will be at a minimum in this mode and the maximum output current of 2 A can be supplied by the LM43602.

8.4.5 Light Load Operation

When the load current is lower than half of the peak-to-peak inductor current in CCM, the LM43602 will operate in Discontinuous Conduction Mode (DCM), also known as Diode Emulation Mode (DEM). In DCM operation, the LS FET is turned off when the inductor current drops to 0 A to improve efficiency. Both switching losses and conduction losses are reduced in DCM, comparing to forced PWM operation at light load.

At even lighter current loads, Pulse Frequency Mode (PFM) is activated to maintain high efficiency operation. When the HS switch ON-time reduces to T_{ON_MIN} or peak inductor current reduces to its minimum $I_{PEAK-MIN}$, the switching frequency will reduce to maintain proper regulation. Efficiency is greatly improved by reducing switching and gate drive losses.

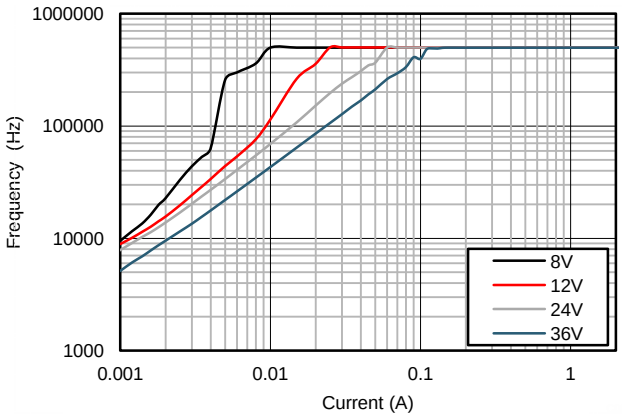

Figure 35. V_{OUT} = 5 V F_s = 500 kHz Pulse Frequency Mode Operation

8.4.6 Self-Bias Mode

For highest efficiency of operation, it is recommended that the BIAS pin be connected directly to V_{OUT} when V_{OUT} ≥ 3.3 V. In this Self-Bias Mode of operation, the difference between the input and output voltages of the internal LDO are reduced and therefore the total efficiency of the LM43602 is improved. These efficiency gains are more evident during light load operation. During this mode of operation, the LM43602 operates with a minimum quiescent current of 27 µA (typical). Please refer to VCC, UVLO and BIAS for more details.

9 Applications and Implementation

9.1 Application Information

The LM43602 is a step down DC-to-DC regulator. It is typically used to convert a higher DC voltage to a lower DC voltage with a maximum output current of 2 A. The following design procedure can be used to select components for the LM43602. Alternately, the WEBENCH® software may be used to generate complete designs. When generating a design, the WEBENCH® software utilizes iterative design procedure and accesses comprehensive databases of components. Please go to ti.com for more details.

This section presents a simplified discussion of the design process.

9.2 Typical Applications

The LM43602 only requires a few external components to convert from a wide voltage range of supply to a fixed output voltage. Figure 36 shows a basic schematic when BIAS is connected to V_{OUT} and this is recommended for $V_{OUT} \geq 3.3$ V. For $V_{OUT} < 3.3$ V, BIAS should be connected to ground, as shown in Figure 37.

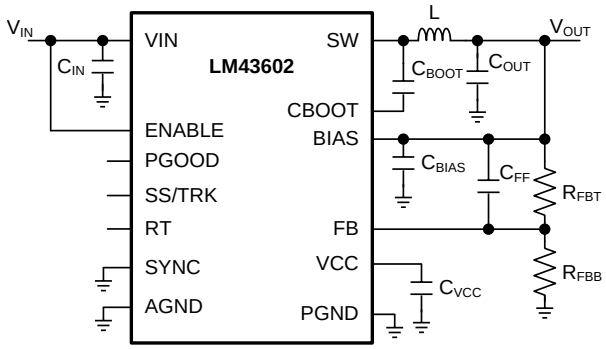

Figure 36. LM43602 Basic Schematic for $V_{OUT} \geq 3.3$ V, tie BIAS to V_{OUT}

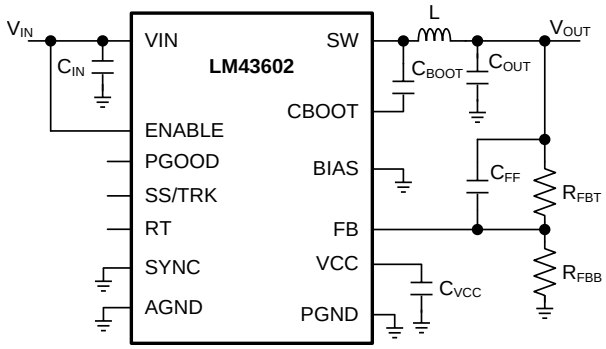

Figure 37. LM43602 Basic Schematic for $V_{OUT} < 3.3$ V, tie BIAS to ground

The LM43602 also integrates a full list of optional features to aid system design requirements such as: precision enable, V_{CC} UVLO, programmable soft-start, output voltage tracking, programmable switching frequency, clock synchronization and power-good indication. Each application can select the features for a more comprehensive design. A schematic with all features utilized is shown in Figure 38.

Typical Applications (continued)

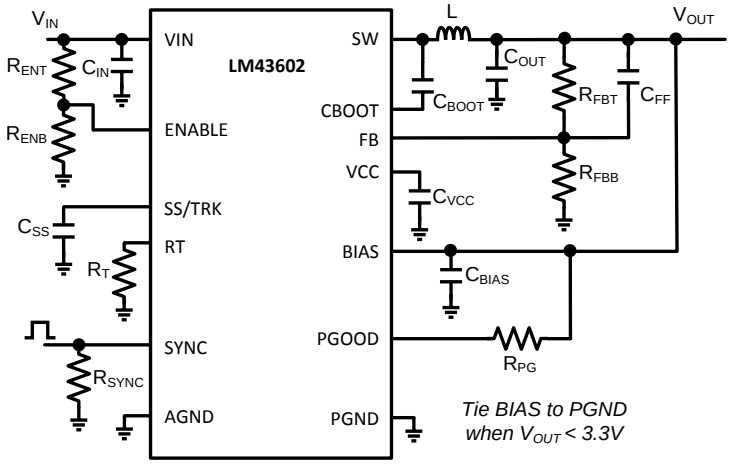

Figure 38. LM43602 Schematic with All Features

The external components have to fulfill the needs of the application, but also the stability criteria of the device's control loop. The LM43602 is optimized to work within a range of external components. The LC output filter's inductance and capacitance have to be considered in conjunction, creating a double pole, responsible for the corner frequency of the converter (see Output Filter And Loop Stability section). Table 2 can be used to simplify the output filter component selection.

Table 2. L, C_{OUT} and C_{FF} Typical Values

Typical Applications (continued)

9.2.1 Design Requirements

Detailed design procedure is described based on a design example. For this design example, use the parameters listed in Table 3 as the input parameters.

Table 3. Design Example Parameters

DESIGN PARAMETER	VALUE
Input Voltage V_{IN}	12 V typical, range from 3.5 V to 36 V
Output Voltage V_{OUT}	3.3 V
Input Ripple Voltage	400 mV
Output ripple voltage	30 mV
Output Current Rating	2 A
Operating Frequency	500 kHz
Soft-start time	10 ms

9.2.2 Detailed Design Procedure

9.2.2.1 Output Voltage Set-Point

The output voltage of the LM43602 device is externally adjustable using a resistor divider network. The divider network is comprised of top feedback resistor R_{FBT} and bottom feedback resistor R_{FBB}. The following equation is used to determine the output voltage of the converter:

$$R_{FBB} = \frac{V_{FB}}{V_{OUT} - V_{FB}} R_{FBT} \quad (11)$$

Choose the value of the R_{FBT} to be 1 MΩ to minimize quiescent current to improve light load efficiency in this application. With the desired output voltage set to be 3.3 V and the V_{FB} = 1.011 V, the R_{FBB} value can then be calculated using Equation 11. The formula yields a value of 434.78 kΩ. Choose the closest available value of 432 kΩ for the R_{FBB}. Please refer to Adjustable Output Voltage for more details.

9.2.2.2 Switching Frequency

The default switching frequency of the LM43602 device is set at 500 kHz when RT pin is open circuit. The switching frequency is selected to be 500 kHz in this application for one less passive components. If other frequency is desired, use Equation 12 to calculate the required value for R_T.

$$R_T(k\Omega) = 40200 / Freq\ (kHz) - 0.6 \quad (12)$$

For 500 kHz, the calculated R_T is 79.8 kΩ and standard value 80.6 kΩ can also be used to set the switching frequency at 500 kHz.

9.2.2.3 Input Capacitors

The LM43602 device requires high frequency input decoupling capacitor(s) and a bulk input capacitor, depending on the application. The typical recommended value for the high frequency decoupling capacitor is 4.7 µF to 10 µF. A high-quality ceramic type X5R or X7R with sufficiency voltage rating is recommended. The voltage rating must be greater than the maximum input voltage. To compensate the derating of ceramic capactors, a voltage rating of twice the maximum input voltage is recommended. Additionally, some bulk capacitance can be required, especially if the LM43602 circuit is not located within approximately 5 cm from the input voltage source. This capacitor is used to provide damping to the voltage spiking due to the lead inductance of the cable or trace. The value for this capacitor is not critical but must be rated to handle the maximum input voltage including ripple. For this design, a 10 µF, X7R dielectric capacitor rated for 100 V is used for the input decoupling capacitor. The equivalent series resistance (ESR) is approximately 3 mΩ, and the current-rating is 3 A. Include a capacitor with a value of 0.1 µF for high-frequency filtering and place it as close as possible to the device pins.

Copyright © 2014, Texas Instruments Incorporated

NOTE

DC Bias effect: High capacitance ceramic capacitors have a DC Bias effect, which will have a strong influence on the final effective capacitance. Therefore the right capacitor value has to be chosen carefully. Package size and voltage rating in combination with dielectric material are responsible for differences between the rated capacitor value and the effective capacitance.

9.2.2.4 Inductor Selection

The first criterion for selecting an output inductor is the inductance itself. In most buck converters, this value is based on the desired peak-to-peak ripple current, Δi_L, that flows in the inductor along with the DC load current. As with switching frequency, the selection of the inductor is a tradeoff between size and cost. Higher inductance gives lower ripple current and hence lower output voltage ripple with the same output capacitors. Lower inductance could result in smaller, less expensive component. An inductance that gives a ripple current of 20% to 40% of the 2 A at the typical supply voltage is a good starting point. ΔI_L = (1/5 to 2/5) x I_{OUT}. The peak-to-peak inductor current ripple can be found by Equation 13 and the range of inductance can be found by Equation 14 with the typical input voltage used as V_{IN}.

$$\Delta i_L = \frac{(V_{IN} - V_{OUT}) \times D}{L \times F_S} \tag{13}$$

$$\frac{(V_{IN} - V_{OUT}) \times D}{0.4 \times F_S \times I_{L-MAX}} \le L \le \frac{(V_{IN} - V_{OUT}) \times D}{0.2 \times F_S \times I_{L-MAX}} \tag{14}$$

D is the duty cycle of the converter which in a buck converter can be approximated as D = V_{IN}/V_{OUT}, assuming no loss power conversion. By calculating in terms of amperes, volts, and megahertz, the inductance value will come out in micro henries. The inductor ripple current ratio is defined by:

$$r = \frac{\Delta i_L}{I_{OUT}} \tag{15}$$

The second criterion is the inductor saturation current rating. The inductor should be rated to handle the maximum load current plus the ripple current:

$$I_{L\text{-}PEAK} = I_{LOAD\text{-}MAX} + \Delta i_L \tag{16}$$

The LM43602 has both valley current limit and peak current limit. During an instantaneous short, the peak inductor current can be high due to a momentary increase in duty cycle. The inductor current rating should be higher than the HS current limit. It is advised to select an inductor with a larger core saturation margin and preferably a softer roll off of the inductance value over load current.

In general, it is preferable to choose lower inductance in switching power supplies, because it usually corresponds to faster transient response, smaller DCR, and reduced size for more compact designs. But too low of an inductance can generate too large of an inductor current ripple such that over current protection at the full load could be falsely triggered. It also generates more conduction loss, since the RMS current is slightly higher relative that with lower current ripple at the same DC current. Larger inductor current ripple also implies larger output voltage ripple with the same output capacitors. With peak current mode control, it is not recommended to have too small of an inductor current ripple. A larger peak current ripple improves the comparator signal to noise ratio.

Once the inductance is determined, the type of inductor must be selected. Ferrite designs have very low core losses and are preferred at high switching frequencies, so design goals can concentrate on copper loss and preventing saturation. Ferrite core material saturates hard, which means that inductance collapses abruptly when the peak design current is exceeded. The ‘hard’ saturation results in an abrupt increase in inductor ripple current and consequent output voltage ripple. Do not allow the core to saturate!

For the design example, a standard 6.8 µH inductor from Wurth, Coiltronics, or Vishay can be used for the 3.3 V output with plenty of current rating margin.

9.2.2.5 Output Capacitor Selection

The device is designed to be used with a wide variety of LC filters. It is generally desired to use as little output capacitance as possible to keep cost and size down. The output capacitor (s), COUT, should be chosen with care since it directly affects the steady state output voltage ripple, loop stability and the voltage over/undershoot during load current transients.

The output voltage ripple is essentially composed of two parts. One is caused by the inductor current ripple going through the Equivalent Series Resistance (ESR) of the output capacitors:

$$\Delta V_{OUT\text{-}ESR} = \Delta i_L \times ESR \tag{17}$$

The other is caused by the inductor current ripple charging and discharging the output capacitors:

$$\Delta V_{OUT\text{-}C} = \Delta i_L / (8 \times F_S \times C_{OUT}) \tag{18}$$

The two components in the voltage ripple are not in phase, so the actual peak-to-peak ripple is smaller than the sum of the two peaks.

Output capacitance is usually limited by transient performance specifications if the system requires tight voltage regulation in the presence of large current steps and fast slew rates. When a fast large load transient happens, output capacitors provide the required charge before the inductor current can slew to the appropriate level. The initial output voltage step is equal to the load current step multiplied by the ESR. VOUT continues to droop until the control loop response increases or decreases the inductor current to supply the load. To maintain a small over- or undershoot during a transient, small ESR and large capacitance are desired. But these also come with higher cost and size. Thus, the motivation is to seek a fast control loop response to reduce the output voltage deviation.

For a given input and output requirement, the following inequality gives an approximation for an absolute minimum output cap required:

$$C_{OUT} > \frac{1}{(F_S \times r \times \Delta V_{OUT} / I_{OUT})} \times \left[\left(\frac{r^2}{12} \times (1 + D') \right) + (D' \times (1 + r)) \right] \tag{19}$$

Along with this for the same requirement, the max ESR should be calculated as per the following inequality

$$ESR < \frac{D'}{F_S \times C_{OUT}} \times \left(\frac{1}{r} + 0.5 \right) \tag{20}$$

where

r = Ripple ratio of the inductor ripple current (ΔI_L / I_{OUT})

ΔV_{OUT} = Target output voltage undershoot

D’ = 1 – Duty cycle

F_S = Switching Frequency

I_{OUT} = Load Current

A general guide line for C_{OUT} range is that C_{OUT} should be larger than the minimum required output capacitance calculated by Equation 19, and smaller than 10 times the minimum required output capacitance or 1 mF. In applications with V_{OUT} less than 3.3 V, it is critical that low ESR output capacitors are selected. This will limit potential output voltage overshoots as the input voltage falls below the device normal operating range. To optimize the transient behavior a feed-forward capacitor could be added in parallel with the upper feedback resistor. For this design example, three 47 µF,10 V, X7R ceramic capacitors are used in parallel.

9.2.2.6 Feed-Forward Capacitor

The LM43602 is internally compensated and the internal R-C values are 400 kΩ and 50 pF respectively. Depending on the V_{OUT} and frequency F_S, if the output capacitor C_{OUT} is dominated by low ESR (ceramic types) capacitors, it could result in low phase margin. To improve the phase boost an external feedforward capacitor C_{FF} can be added in parallel with R_{FBT}. C_{FF} is chosen such that phase margin is boosted at the crossover frequency without C_{FF}. A simple estimation for the crossover frequency without C_{FF} (f_x) is shown in Equation 21, assuming C_{OUT} has very small ESR.

Copyright © 2014, Texas Instruments Incorporated

$$f_x = \frac{4.35}{V_{OUT} \times C_{OUT}} \quad (21)$$

The following equation for C_{FF} was tested:

$$C_{FF} = \frac{1}{2\pi f_x} \times \frac{1}{\sqrt{R_{FBT} \times (R_{FBT} \,//\, R_{FBB})}} \quad (22)$$

This equation indicates that the crossover frequency is geometrically centered on the zero and pole frequencies caused by the C_{FF} capacitor.

For designs with higher ESR, C_{FF} is not neeed when C_{OUT} has very high ESR and C_{FF} calculated from Equation 22 should be reduced with medium ESR. Table 2 can be used as a quick starting point.

For the application in this design example, a 100 pF COG capacitor is selected.

9.2.2.7 Bootstrap Capacitors

Every LM43602 design requires a bootstrap capacitor, C_{BOOT}. The recommended bootstrap capacitor is 0.47 µF and rated at 6.3 V or higher. The bootstrap capacitor is located between the SW pin and the CBOOT pin. The bootstrap capacitor must be a high-quality ceramic type with X7R or X5R grade dielectric for temperature stability.

9.2.2.8 VCC Capacitor

The VCC pin is the output of an internal LDO for LM43602. The input for this LDO comes from either VIN or BIAS (please refer to Functional Block Diagram for LM43602). To insure stability of the part, place a minimum of 2.2 µF, 10 V capacitor from this pin to ground.

9.2.2.9 BIAS Capacitors

For an output voltage of 3.3 V and greater, the BIAS pin can be connected to the output in order to increase light load efficiency. This pin is an input for the VCC LDO. When BIAS is not connected, the input for the VCC LDO will be internally connected into VIN. Since this is an LDO, the voltage differences between the input and output will affect the efficiency of the LDO. If necessary, a capacitor with a value of 1 µF can be added close to the BIAS pin as an input capacitor for the LDO.

9.2.2.10 Soft-Start Capacitors

The user can left the SS/TRK pin floating and the LM43602 will implement a soft start time of 4.1 ms typically. In order to use an external soft start capacitor, the capacitor should be sized such that the soft start time will be longer than 4.1 ms. Use the following equation in order to calculate the soft start capacitor value:

$$C_{SS} = I_{SSC} \times t_{SS} \quad (23)$$

Where,

C_{SS} = Soft start capacitor value (µF)

I_{SS} = Soft start charging current (µA)

t_{SS} = Desired soft start time (s)

For the desired soft start time of 10 ms and soft start charging current of 2.0 µA, the equation above yield a soft start capacitor value of 0.020 µF.

9.2.2.11 Under Voltage Lockout Set-Point

The undervoltage lockout (UVLO) is adjusted using the external voltage divider network of R_{ENT} and R_{ENB}. R_{ENT} is connected between VIN and the EN pin of the LM43602 device. R_{ENB} is connected between the EN pin and the GND pin. The UVLO has two thresholds, one for power up when the input voltage is rising and one for power down or brown outs when the input voltage is falling. The following equation can be used to determine the VIN (UVLO) level.

$$V_{EN} = V_{IN\text{-}UVLO} \times R_{ENB} / (R_{ENB} + R_{ENT}) \quad (24)$$

Copyright © 2014, Texas Instruments Incorporated

The EN rising threshold for LM43602 is set to be 2.2 V. Choose the value of R_{ENB} to be 1MΩ to minimize input current going into the converter. If the desired VIN (UVLO) level is at 3.5 V, then the value of R_{ENT} can be calculated using the equation above and yield a value of 590 kΩ.

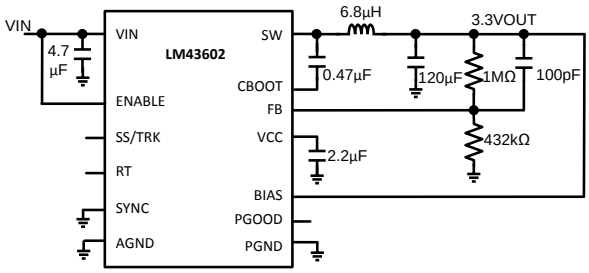

9.2.2.12 PGOOD

A typical pull-up resistor value is 10 kΩ to 100 kΩ from PGOOD pin to a voltage no higher than 12 V. If it is desired to pull up PGOOD pin to a voltage higher than 12 V, a resistor can be added from PGOOD pin to ground to divide the voltage seen by the PGOOD pin to a value no higher than 12 V.

10 Power Supply Recommendations

The LM43602 is designed to operate from an input voltage supply range between 3.5 V and 60 V. This input supply should be well regulated and able to withstand maximum input current and maintain a stable voltage. The resistance of the input supply rail should be low enough that an input current transient does not cause a high enough drop at the LM43602 supply voltage that can cause a false UVLO fault triggering and system reset.

If the input supply is located more than a few inches from the LM43602 additional bulk capacitance may be required in addition to the ceramic bypass capacitors. The amount of bulk capacitance is not critical, but a 47 µF or 100 µF electrolytic capacitor is a typical choice.

11 Layout

The performance of any switching converter depends as much upon the layout of the PCB as the component selection. The following guidelines will help users design a PCB with the best power conversion performance, thermal performance, and minimized generation of unwanted EMI.

11.1 Layout Guidelines

1. Place ceramic high frequency bypass C_{IN} as close as possible to the LM43602 VIN and PGND pins. Grounding for both the input and output capacitors should consist of localized top side planes that connect to the PGND pins and PAD.
2. Place bypass capacitors for VCC and BIAS close to the pins and ground the bypass capacitors to device ground.
3. Minimize trace length to the FB pin net. Both feedback resistors, R_{FBT} and R_{FBB} should be located close to the FB pin. Place Cff directly in parallel with R_{FBT}. If V_{OUT} accuracy at the load is important, make sure V_{OUT} sense is made at the load. Route V_{OUT} sense path away from noisy nodes and preferably through a layer on the other side of a shieldig layer.
4. Use ground plane in one of the middle layers as noise shielding and heat dissipation path.
5. Have a single point ground connection to the plane. The ground connections for the feedback, soft-start, and enable components should be routed to the ground plane. This prevents any switched or load currents from flowing in the analog ground traces. If not properly handled, poor grounding can result in degraded load regulation or erratic output voltage ripple behavior.
6. Make V_{IN}, V_{OUT} and ground bus connections as wide as possible. This reduces any voltage drops on the input or output paths of the converter and maximizes efficiency.
7. Provide adequate device heat-sinking. Use an array of heat-sinking vias to connect the exposed pad to the ground plane on the bottom PCB layer. If the PCB has multiple copper layers, these thermal vias can also be connected to inner layer heat-spreading ground planes. Ensure enough copper area is used for heat-sinking to keep the junction temperature below 125°C.

11.1.1 Compact Layout for EMI Reduction

Radiated EMI is generated by the high di/dt components in pulsing currents in switching converters. The larger area covered by the path of a pulsing current, the more EMI is generated. The key to minimize radiated EMI is to identify pulsing current path and minimize the area of the path. In Buck converters,the pulsing current path is from the V_{IN} side of the input capacitors to HS switch, to the LS switch, and then return to the ground of the input capacitors, as shown in Figure 63.

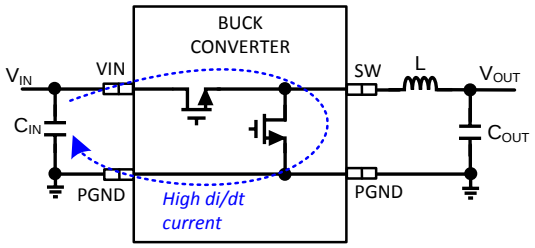

Figure 63. Buck Converter High Δi/Δt Path

Layout Guidelines (continued)

High frequency ceramic bypass capacitors at the input side provide primary path for the high di/dt components of the pulsing current. Placing ceramic bypass capacitor(s) as close as possible to the VIN and PGND pins is the key to EMI reduction.

The SW pin connecting to the inductor should be as short as possible, and just wide enough to carry the load current without excessive heating. Short, thick traces or copper pours (shapes) should be used for high current condution path to minimize parasitic resistance. The output capacitors should be place close to the V_{OUT} end of the inductor and closely grounded to PGND pin and exposed PAD.

The bypass capacitors on VCC and BIAS pins should be placed as close as possible to the pins respectively and closely grounded to PGND and the exposed PAD.

11.1.2 Ground Plane and Thermal Considerations

It is recommended to use one of the middle layers as a solid ground plane. Ground plane provides shielding for sensitive circuits and traces. It also provides a quiet reference potential for the control circuitry. The AGND and PGND pins should be connected to the ground plane using vias right next to the bypass capacitors. PGND pins are connected to the source of the internal LS switch. They should be connected directly to the grounds of the input and output capacitors. The PGND net contains noise at switching frequency and may bounce due to load variations. PGND trace, as well as PVIN and SW traces, should be constrained to one side of the ground plane. The other side of the ground plane contains much less noise and should be used for sensitive routes.

It is recommended to provide adequate device heat sinking by utilizing the PAD of the IC as the primary thermal path. Use a minimum 4 by 4 array of 10 mil thermal vias to connect the PAD to the system ground plane heat sink. The vias should be evenly distributed under the PAD. Use as much copper as possible for system ground plane on the top and bottom layers for the best heat dissipation. Use a four-layer board with the copper thickness for the four layers, starting from the top one, 2 oz / 1 oz / 1 oz / 2 oz. Four layer boards with enough copper thickness provides low current conduction impedance, proper shielding and lower thermal resistance.

The thermal characteristics of the LM46002 are specified using the parameter RθJA, which characterize the junction temperature of the silicon to the ambient temperature in a specific system. Although the value of θ_{JA} is dependant on many variables, it still can be used to approximate the operating junction temperature of the device. To obtain an estimate of the device junction temperature, one may use the following relationship:

$$T_J = P_D \times \theta_{JA} + T_A \quad (25)$$

where

T_J = Junction temperature in °C

$P_D = V_{IN} \times I_{IN} \times (1 - \text{Efficiency}) - 1.1 \times I_{OUT} \times DCR$

DCR = Inductor DC parasitic resistance in Ω

θ_{JA} = Junction-to-ambient thermal resistance of the device in °C/W

T_A = Ambient temperature in °C.

The maximum operating junction temperature of the LM43602 is 125°C. θ_{JA} is highly related to PCB size and layout, as well as enviromental factors such as heat sinking and air flow. Figure 64 shows measured results of RθJA with different copper area on a 2-layer board and a 4-layer board.

Copyright © 2014, Texas Instruments Incorporated

Layout Guidelines (continued)

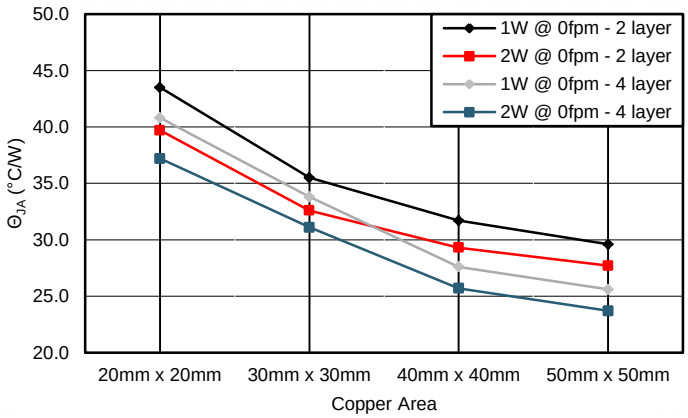

Figure 64. θ_{JA} vs Copper Area
2oz Copper on Outer Layers and 1oz Copper on Inner Layers

11.1.3 Feedback Resistors

To reduce noise sensitivity of the output voltage feedback path, it is important to place the resistor divider and C_{FF} close to the FB pin, rather than close to the load. The FB pin

is the input to the error amplifier, so it is a high impedance node and very sensitive to noise. Placing the resistor divider and C_{FF} closer to the FB pin reduces the trace length of FB signal and reduces noise coupling. The output node is a low impedance node, so the trace from V_{OUT} to the resistor divider can be long if short path is not available.

If voltage accuracy at the load is important, make sure voltage sense is made at the load. Doing so will correct for voltage drops along the traces and provide the best output accuracy. The voltage sense trace from the load to the feedback resistor divider should be routed away from the SW node path and the inductor to avoid contaminating the feedback signal with switch noise, while also minimizing the trace length. This is most important when high value resistors are used to set the output voltage. This provides further shielding for the voltage feedback path from EMI noises.

PWP (R–PDSO–G16) PowerPAD™ SMALL PLASTIC OUTLINE

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.
TBD: The Pb-Free/Green conversion plan has not been defined.
Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as “components”) are sold subject to TI’s terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI’s terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers’ products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers’ products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI’s goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or “enhanced plastic” are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have ***not*** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

Компания «ЭлектроПласт» предлагает заключение долгосрочных отношений при поставках импортных электронных компонентов на взаимовыгодных условиях!

Наши преимущества:

- Оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов;
- Поставка более 17-ти миллионов наименований электронных компонентов;
- Поставка сложных, дефицитных, либо снятых с производства позиций;
- Оперативные сроки поставки под заказ (от 5 рабочих дней);
- Экспресс доставка в любую точку России;
- Техническая поддержка проекта, помощь в подборе аналогов, поставка прототипов;
- Система менеджмента качества сертифицирована по Международному стандарту ISO 9001;
- Лицензия ФСБ на осуществление работ с использованием сведений, составляющих государственную тайну;
- Поставка специализированных компонентов (Xilinx, Altera, Analog Devices, Intersil, Interpoint, Microsemi, Aeroflex, Peregrine, Syfer, Eurofarad, Texas Instrument, Miteq, Cobham, E2V, MA-COM, Hittite, Mini-Circuits,General Dynamics и др.);

Помимо этого, одним из направлений компании «ЭлектроПласт» является направление «Источники питания». Мы предлагаем Вам помощь Конструкторского отдела:

- Подбор оптимального решения, техническое обоснование при выборе компонента;
- Подбор аналогов;
- Консультации по применению компонента;
- Поставка образцов и прототипов;
- Техническая поддержка проекта;
- Защита от снятия компонента с производства.
