# Nawbit <br> 5V/3.3V or Adjustable, High-Efficiency, Low-Dropout, Step-Down DC-DC Controllers 

## General Description

The MAX1649/MAX1651 BiCMOS, step-down, DC-DC switching controllers provide high efficiency over loads ranging from 1 mA to more than 2.5 A . A unique, currentlimited pulse-frequency-modulated (PFM) control scheme gives these devices the benefits of pulse-width-modulation (PWM) converters (high efficiency at heavy loads), while using only $100 \mu \mathrm{~A}$ of supply current (vs. 2 mA to 10 mA for PWM converters). Dropout performance down to 300 mV is provided by a high switch duty cycle ( $96.5 \%$ ) and a low current-sense threshold (110mV).
A high switching frequency (up to 300 kHz ) allows these devices to use miniature external components.
The MAX1649/MAX1651 have dropout voltages less than 0.3 V at 500 mA and accept input voltages up to 16V. Output voltages are preset at 5V (MAX1649), or 3.3V (MAX1651). They can also be adjusted to any voltage from 1.5 V to the input voltage by using two resistors
These step-down controllers drive external P-channel MOSFETs at loads greater than 12.5 W . If less power is required, use the MAX639/MAX640/MAX653 step-down converters with on-chip FETs, which allow up to a 225 mA load current.

Applications
PDAs
High-Efficiency Step-Down Regulation
5V-to-3.3V Green PC Applications
Battery-Powered Applications
Typical Operating Circuit

- More than $90 \%$ Efficiency (10mA to 1.5A Loads)
- More than 12.5W Output Power
- Less than 0.3 V Dropout Voltage at 500 mA
- $100 \mu \mathrm{~A}$ Max Quiescent Supply Current
- 5hA Max Shutdown Supply Current
- 16V Max Input Voltage
- 5V (MAX1649), 3.3V (MAX1651), or Adjustable Output Voltage
- Current-Limited Control Scheme
- Up to 300 kHz Switching Frequency
- Up to 96.5\% Duty Cycle

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :--- |
| 1 | OUT | Sense Input for fixed 5V or 3.3V output operation. OUT is internally connected to the on-chip voltage divider. <br> Although it is connected to the output of the circuit, OUT does not supply current. Leave OUT unconnected for <br> adjustable-output operation. |
| 2 | FB | Feedback Input. Connect to GND for fixed-output operation. Connect a resistor divider between OUT, FB, and <br> GND for adjustable-output operation. See Setting the Output Voltage section. |
| 3 | SHDN | Active-High Shutdown Input. Part is placed in shutdown when SHDN is driven high. In shutdown mode, the refer- <br> ence, output, and external MOSFET are turned off. Connect to GND for normal operation. |
| 4 | REF | 1.5V Reference Output that can source 100 AA. Bypass with 0.1 $\mu \mathrm{FF}$. |
| 5 | V+ | Positive Power-Supply Input |
| 6 | CS | Current-Sense Input. Connect current-sense resistor between V+ and CS. When the voltage across the resistor <br> equals the current-limit trip level, the external MOSFET is turned off. |
| 7 | EXT | Gate Drive for External P-Channel MOSFET. EXT swings between V+ and GND. |
| 8 | GND | Ground |

Figure 1. Typical Application Circuit

## Detailed Description

The MAX1649/MAX1651 are BiCMOS, step-down, switch-mode power-supply controllers that provide adjustable and fixed outputs of 5 V and 3.3 V , respectively. Their unique control scheme combines the advantages of pulse-frequency-modulation (low supply current) and pulse-width-modulation (high efficiency at high loads). An external P-channel power MOSFET allows peak currents in excess of 3 A , increasing the output current capability over previous PFM devices. Figure 2 is the block diagram.

The MAX1649/MAX1651 offer four main improvements over prior solutions:

1) The converters operate with miniature surface-mount inductors, due to their 300 kHz switching frequency.
2) The current-limited PFM control scheme allows greater than $90 \%$ efficiencies over a wide range of load currents ( 10 mA to 1.5 A ).
3) Dropout voltage has been reduced to less than 300mV for many applications.
4) The quiescent supply current is only $100 \mu \mathrm{~A}$.

## PFM Control Scheme

The MAX1649/MAX1651 use a proprietary, current-limited PFM control scheme. As with traditional PFM converters, the external power MOSFET is turned on when the voltage comparator senses that the output is out of regulation. However, unlike traditional PFM converters, switching is accomplished through the combination of a peak current limit and a pair of one-shots that set the maximum switch on-time $(32 \mu s)$ and minimum switch off-time $(1.1 \mu \mathrm{~s})$. Once off, the off-time one-shot holds the switch off for $1.1 \mu \mathrm{~s}$. After this minimum time, the switch either 1) stays off if the output is in regulation, or 2) turns on again if the output is out of regulation.

The MAX1649/MAX1651 also limit the peak inductor current, which allows them to run in continuous-conduction mode and maintain high efficiency with heavy loads (Figure 3). This current-limiting feature is a key component of the control circuitry. Once turned on, the switch stays on until either 1) the maximum on-time one-shot turns it off ( $32 \mu \mathrm{~s}$ later), or 2 ) the current limit is reached. EXT swings from $V+$ to GND and provides the drive output for an external P-channel power MOSFET.

## 5V/3.3V or Adjustable, High-Efficiency, Low-Dropout, Step-Down DC-DC Controllers

Figure 2. Block Diagram

## Shutdown Mode

When SHDN is high, the MAX1649/MAX1651 enter shutdown mode. In this mode, the internal biasing circuitry is turned off (including the reference) and the supply current drops to less than $5 \mu \mathrm{~A}$. EXT goes high, turning off the external MOSFET. SHDN is a logic-level input. Connect SHDN to GND for normal operation.

## Quiescent Current

In normal operation, the device's typical quiescent current is $78 \mu \mathrm{~A}$. In an actual application, even with no load, additional current is drawn to supply external feedback resistors (if used) and the diode and capacitor leakage currents. In the circuit of Figure 1, with $\mathrm{V}+$ at 5 V and VOUT at 3.3 V , typical no-load supply current for the entire circuit is $90 \mu \mathrm{~A}$.

# 5V/3.3V or Adjustable, High-Efficiency, Low-Dropout, Step-Down DC-DC Controllers 

Figure 3. MAX1649 Continuous-Conduction Mode, Heavy Load-Current Waveform ( $500 \mathrm{~mA} /$ div)

## Modes of Operation

When delivering high output currents, the MAX1649/ MAX1651 operate in continuous-conduction mode. In this mode, current always flows in the inductor, and the control circuit adjusts the switch duty cycle to maintain regulation without exceeding the switch current capability (Figure 3). This provides excellent load-transient response and high efficiency.
In discontinuous-conduction mode, current through the inductor starts at zero, rises to a peak value, then ramps down to zero. Although efficiency is still excellent, the output ripple increases slightly, and the switch waveform exhibits ringing (at the inductor's self-resonant frequency). This ringing is to be expected and poses no operational problems.

## Dropout

The MAX1649/MAX1651 are in dropout when the input voltage ( $\mathrm{V}+$ ) is low enough that the output drops below the minimum output voltage specification (see Electrical Characteristics). The dropout voltage is the difference between the input and output voltage when dropout occurs. See the Typical Operating Characteristics for the Dropout Voltage vs. Load Current and Dropout Voltage vs. Temperature graphs.

Figure 4. Adjustable-Output Operation

## Design Procedure

## Setting the Output Voltage

The MAX1649/MAX1651 are preset for 5 V and 3.3 V output voltages, respectively; tie FB to GND for fixed-output operation. They may also be adjusted from 1.5 V (the reference voltage) to the input voltage, using external resistors R2 and R3 configured as shown in Figure 4. For adjustable-output operation, $150 \mathrm{k} \Omega$ is recommended for resistor R3-high enough to avoid wasting energy, yet low enough to avoid RC delays caused by parasitic capacitance at $F B$. R2 is given by:

$$
R 2=R 3 \times\left(\frac{V_{\text {OUT }}}{V_{\text {REF }}}-1\right)
$$

where $\operatorname{VREF}=1.5 \mathrm{~V}$.
When using external resistors, it does no harm to connect OUT and the output together, or to leave OUT unconnected.

Current-Sense Resistor Selection
The current-sense resistor limits the peak switch current to $110 \mathrm{mV} / \mathrm{RSE}$ SSE, where RSENSE is the value of the current-sense resistor, and 110 mV is the currentlimit trip level (see Electrical Characteristics).

# 5V/3.3V or Adjustable, High-Efficiency, Low-Dropout, Step-Down DC-DC Controllers 

To maximize efficiency and reduce the size and cost of external components, minimize the peak current. However, since the available output current is a function of the peak current, the peak current must not be too low.
To choose the proper current-sense resistor for a particular output voltage, determine the minimum input voltage and the maximum load current. Next, referring to Figures 5 a or 5 b , using the minimum input voltage, find the curve with the largest sense resistor that provides sufficient output current. It is not necessary to perform worst-case calculations. These curves take into account the sense-resistor ( $\pm 5 \%$ ) and inductor $(47 \mu \mathrm{H} \pm 10 \%)$ values, the diode drop (0.4), and the IC's current-sense trip level ( 85 mV ); an external MOSFET on-resistance of $0.07 \Omega$ is assumed for $V_{G S}=-5 \mathrm{~V}$.

Standard wire-wound and metal-film resistors have an inductance high enough to degrade performance. Surface-mount (chip) resistors have very little inductance and are well suited for use as current-sense resistors. A U-shaped wire resistor made by IRC works well in through-hole applications. Because this resistor is a band of metal shaped as a "U", its inductance is less than 10 nH (an order of magnitude less than metal film resistors). Resistance values between $5 \mathrm{~m} \Omega$ and $0.1 \Omega$ are available (see Table 1).

Inductor Selection
The MAX1649/MAX1651 operate with a wide range of inductor values, although for most applications coils between $10 \mu \mathrm{H}$ and 68 H take best advantage of the con-
trollers' high switching frequency. With a high inductor value, the MAX1649/MAX1651 will begin continuous-current operation (see Detailed Description) at a lower fraction of full-load current. In general, smaller values produce higher ripple (see below) while larger values require larger size for a given current rating.
In both the continuous and discontinuous modes, the lower limit of the inductor is important. With a too-small inductor value, the current rises faster and overshoots the desired peak current limit because the current-limit comparator has a finite response time (300ns). This reduces efficiency and, more importantly, could cause the current rating of the external components to be exceeded. Calculate the minimum inductor value as follows:

$$
\mathrm{L}(\min )=\frac{(\mathrm{V}+(\max )-\mathrm{VOUT}) \times 0.3 \mu \mathrm{~s}}{\Delta \mid \times \mathrm{I} I \mathrm{M}}
$$

where $\Delta l$ is the inductor-current overshoot factor, lLIM $=\mathrm{V}_{\mathrm{CS}} /$ RSENSE, and $0.3 \mu \mathrm{~s}$ is the time it takes the comparator to switch. Set $\Delta I=0.1$ for an overshoot of $10 \%$.
For highest efficiency, use a coil with low DC resistance; a value smaller than $0.1 \mathrm{~V} / \mathrm{L}$ LIM works best. To minimize radiated noise, use a toroid, pot core, or shielded-bobbin inductor. Inductors with a ferrite core or equivalent are recommended. Make sure the inductor's saturation-current rating is greater than ILIM(max). However, it is generally acceptable to bias the inductor into saturation by about 20\% (the point where the inductance is $20 \%$ below its nominal value).

Figure 5b. MAX1651 Current-Sense Resistor Graph

The peak current of Figure 1 is 2.35 A for a 1.5 A output. The inductor used in this circuit is specified to drop by $10 \%$ at 2.2A (worst case); a curve provided by the manufacturer shows that the inductance typically drops by $20 \%$ at 2.7 A . Using a slightly underrated inductor can sometimes reduce size and cost, with only a minor impact on efficiency.
Table 1 lists inductor types and suppliers for various applications. The efficiencies of the listed surfacemount inductors are nearly equivalent to those of the larger size through-hole versions.

## Diode Selection

The MAX1649/MAX1651's high switching frequency demands a high-speed rectifier. Schottky diodes, such as the 1N5817 through 1N5823 (and their surfacemount equivalents), are recommended. Choose a diode with an average current rating equal to or greater than ILIM (max) and a voltage rating higher than $V+(\max )$.

External Switching Transistor The MAX1649/MAX1651 drive P-channel enhancementmode MOSFET transistors only. The choice of power transistor is primarily dictated by the input voltage and the peak current. The transistor's on-resistance, gatesource threshold, and gate charge must also be appropriately chosen. The drain-to-source and gate-tosource breakdown voltage ratings must be greater than $\mathrm{V}+$. The total gate-charge specification is normally not
critical, but values should be less than 100 nC for best efficiency. The MOSFET should be capable of handling the peak current and, for maximum efficiency, have a very low on-resistance at that current. Also, the onresistance must be low for the minimum available $\mathrm{VGS}_{\mathrm{G}}$, which equals $V+(\min )$. Select a transistor with an onresistance between $50 \%$ and $100 \%$ of the currentsense resistor. The Si9430 transistor chosen for the Typical Operating Circuit has a drain-to-source rating of -20 V and a typical on-resistance of $0.070 \Omega$ at 2 A with $V_{G S}=-4.5 \mathrm{~V}$. Tables 1 and 2 list suppliers of switching transistors suitable for use with these devices.

## Capacitor Selection Output Filter Capacitor

The primary criterion for selecting the output filter capacitor is low equivalent series resistance (ESR), rather than high capacitance. An electrolytic capacitor with low enough ESR will automatically have high enough capacitance. The product of the inductor-current variation and the output filter capacitor's ESR determines the amplitude of the high-frequency ripple seen on the output voltage. When a $330 \mu \mathrm{~F}, 10 \mathrm{~V}$ Sprague surface-mount capacitor (595D series) with $E S R=0.15 \Omega$ is used, 40 mV of output ripple is typically observed when stepping down from 10 V to 5 V at 1 A . The output filter capacitor's ESR also affects efficiency. Again, low-ESR capacitors perform best. Table 1 lists some suppliers of low-ESR capacitors.

Input Bypass Capacitor
The input bypass capacitor reduces peak currents drawn from the voltage source, and also reduces the amount of noise at the voltage source caused by the switching action of the MAX1649/MAX1651. The input voltage source impedance determines the size of the capacitor required at the $V+$ input. As with the output filter capacitor, a low-ESR capacitor is recommended. Bypass the IC separately with a $0.1 \mu \mathrm{~F}$ ceramic capacitor placed close to the $\mathrm{V}+$ and GND pins.

Reference Capacitor
Bypass REF with a $0.1 \mu$ F or larger capacitor.

## Package Information

For the latest package outline information and land patterns, go to www.maxim-ic.com/packages.

| PACKAGE TYPE | PACKAGE CODE | DOCUMENT NO. |
| :---: | :---: | :---: |
| 8 PDIP | P8-2 | $\underline{\mathbf{2 1 - 0 0 4 1}}$ |
| 8 SO | $\mathrm{S} 8-4$ | $\underline{\mathbf{2 1 - 0 0 4 3}}$ |

## Layout Considerations

Proper PC board layout is essential because of high current levels and fast switching waveforms that radiate noise. Minimize ground noise by connecting the anode of the rectifier, the input bypass capacitor ground lead, and the output filter capacitor ground lead to a single point ("star" ground configuration). A ground plane is recommended. Also minimize lead lengths to reduce stray capacitance, trace resistance, and radiated noise. In particular, the traces connected to FB (if an external resistor divider is used) and EXT must be short. Place the $0.1 \mu \mathrm{~F}$ ceramic bypass capacitor as close as possible to the $\mathrm{V}+$ and GND pins.

MAX1649/MAX1651 vs. MAX649/MAX651 The MAX1649 and MAX1651 are pin compatible with the MAX649 and MAX651, but have been optimized for improved dropout performance and efficiency-particularly with low input voltages. The MAX1649/MAX1651 feature increased maximum switch duty cycle ( $96.5 \%$ ) and reduced current-limit sense voltage ( 110 mV ). Their predecessors, the MAX649/MAX651, use a higher two-step ( $210 \mathrm{mV} / 110 \mathrm{mV}$ ) current-limit sense voltage to provide tighter current-sense accuracy and reduced inductor peak current at light loads.

000 «ниоКРсистемс» - это оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов. Реализуемая нашей компанией продукция насчитывает более полумиллиона наименований.

Благодаря этому наша компания предлагает к поставке практически не ограниченный ассортимент компонентов как оптовыми, мелкооптовыми партиями, так и в розницу.

Благодаря развитой сети поставщиков, помогаем в поиске и приобретении экзотичных или снятых с производства компонентов.

Наша компания это:

- Гарантия качества поставляемой продукции
- Широкий ассортимент
- Минимальные сроки поставок
- Техническая поддержка
- Подбор комплектации
- Индивидуальный подход
- Гибкое ценообразование
- Работаем по 275 ФЗ
